

2 SAML V2.0 Metadata Interoperability Profile

Working Draft 01, 1 August 2008

4 5	Specification URIs: TBD
6 7	Technical Committee: OASIS Security Services TC
8 9 10	Chair(s): Hal Lockhart, BEA Systems, Inc. Brian Campbell, Ping Identity Corporation
11 12	Editors: Scott Cantor, Internet2
13 14 15 16	Abstract: This profile describes a set of rules for SAML metadata producers and consumers to follow such that federated relationships can be interoperably provisioned, and controlled at runtime in a secure, understandable, and self-contained fashion.
17 18 19 20	Status This document was last revised or approved by the SSTC on the above date. The level of approval is also listed above. Check the current location noted above for possible later revisions of this document. This document is updated periodically on no particular schedule.
21 22 23	TC members should send comments on this specification to the TC's email list. Others should send comments to the TC by using the "Send A Comment" button on the TC's web page at http://www.oasis-open.org/committees/security.
24 25 26	For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the IPR section of the TC web page (http://www.oasis-open.org/committees/security/ipr.php).
27 28	The non-normative errata page for this specification is located at http://www.oasis-open.org/committees/security.

93 1 Introduction

The SAML V2.0 metadata specification [SAML2Meta] defines an XML schema and a set of basic 94 processing rules intended to facilitate the use of SAML profiles, and generally any profile or specification 95 involving SAML. Practical experience has shown that the most complex aspects of implementing most 96 SAML profiles, and obtaining interoperability between such implementations, are in the areas of 97 provisioning federated relationships between deployments, and establishing the validity of cryptographic 98 signatures and handshakes. Because the metadata specification was largely intended to solve those 99 exact problems, a conclusion can be reached that additional profiling is needed to improve and clarify the 100 use of metadata in addressing those aspects of deployment. 101

This profile is the product of the implementation experience of several SAML solution providers and has been widely deployed and successfully used in furtherance of the goal of scaling deployment beyond small numbers into the hundreds and thousands of sites, without sacrificing security in doing so.

1.1 Notation

105

110

111

112

113

114

115 116

117 118

119

120

106 This specification uses normative text.

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this specification are to be interpreted as described in [RFC2119]:

...they MUST only be used where it is actually required for interoperation or to limit behavior which has potential for causing harm (e.g., limiting retransmissions)...

These keywords are thus capitalized when used to unambiguously specify requirements over protocol and application features and behavior that affect the interoperability and security of implementations. When these words are not capitalized, they are meant in their natural-language sense.

```
Listings of XML schemas appear like this.

Example code listings appear like this.
```

Conventional XML namespace prefixes are used throughout the listings in this specification to stand for their respective namespaces as follows, whether or not a namespace declaration is present in the example:

Prefix	XML Namespace	Comments
saml:	urn:oasis:names:tc:SAML:2.0:assertion	This is the SAML V2.0 assertion namespace defined in the SAML V2.0 core specification [SAML2Core].
md:	urn:oasis:names:tc:SAML:2.0:metadata	This is the SAML V2.0 metadata namespace defined in the SAML V2.0 metadata specification [SAML2Meta].
ds:	http://www.w3.org/2000/09/xmldsig#	This is the XML Signature namespace [XMLSig].
xsd:	http://www.w3.org/2001/XMLSchema	This namespace is defined in the W3C XML Schema specification [Schema1]. In schema listings, this is the default namespace and no prefix is shown.
xsi:	http://www.w3.org/2001/XMLSchema-instance	This is the XML Schema namespace for schema-related markup that appears in XML instances [Schema1].

- 121 This specification uses the following typographical conventions in text: <SAMLElement>,
- 122 <ns:ForeignElement>, Attribute, **Datatype**, OtherCode.

1.4 Conformance

1.4.1 SAML V2.0 Metadata Interoperability Profile

- A metadata producer conforms to this profile if it can produce metadata consistent with the normative text in section 2.5.
- A metadata consumer conforms to this profile if it can "accept" metadata in accordance with section 2.3
- and process it consistent with the normative text in section 2.6.

2 SAML V2.0 Metadata Interoperability Profile

159 2.1 Required Information

- 160 Identification: urn:oasis:names:tc:SAML:2.0:profiles:metadata-iop
- 161 Contact information: security-services-comment@lists.oasis-open.org
- 162 **Description:** Given below.
- 163 Updates: None.

164

175

187

193

2.2 Profile Overview

- 165 The SAML V2.0 profiles [SAML2Prof] and metadata [SAML2Meta] specifications, and subsequent profiles
- within OASIS and in other communities, describe the use of SAML metadata as a means of describing
- deployment capabilities and providing partners with information about endpoints, keys, profile support,
- processing requirements, etc.
- 169 This profile extends these practices by guaranteeing that a given metadata document will be consistently
- interpreted by any conforming implementation of higher level profiles. To this end, it requires that
- metadata be usable as a self-contained vehicle for communicating trust such that a user of a conforming
- implementation can be guaranteed that any and all rules for processing digital signatures, encrypted XML,
- and transport layer cryptography (e.g. TLS/SSL [RFC4346]) can be derived from the metadata alone, with
- no additional trust requirements imposed.

2.3 Metadata Acceptance

- 176 This profile does not seek to constrain the method by which metadata is published or acquired, but only its
- content and interpretation. It is assumed that, subject to the security and deployment requirements of the
- 178 participants, some means of exchanging metadata exists that results in the "acceptance" of metadata by a
- consumer. Acceptance in this profile is defined as an explicit treatment of everything in the metadata as
- 180 "true", for the purposes of the metadata consumer's operational behavior.
- In other words, this profile does not define how metadata is exchanged or how and why it is trusted, but
- rather assumes that it is exchanged and trusted, and proceeds from that starting point. Dynamic
- exchange (as described in [SAML2Meta]), manual exchange, the aggregation and signing of metadata by
- third parties, or any other mechanism, can be used in conjunction with this profile.
- The rest of this profile deals with the requirements for producing metadata that will be accepted, and a
- 186 consumer's obligations having accepted it.

2.4 Other Assumptions

- An additional assumption is necessitated by the inability of SAML metadata to express authentication
- 189 requirements of back-channel communications between SAML entities, such as the SAML SOAP binding
- 190 [SAML2Bind]. In lieu of extending metadata to capture such requirements, this profile assumes that such
- communications are secured by means of some combination of TLS/SSL and digital signing. If this
- assumption does not hold, this profile might need supplementing in some scenarios.

2.5 Metadata Producer Requirements

- A producer of metadata that adheres to this profile may be an actual participant in a SAML (or other)
- 195 profile, or an aggregator of metadata describing many such participants. In either case, the content of the

11 draft-sstc-metadata-iop-01

- metadata itself is independent of its source and MUST stand alone as a description of the cryptographic
- requirements for securely communicating with the entity (or entities) described therein, to the extent that
- the constructs of the SAML V2.0 metadata specification [SAML2Meta] can express these requirements.
- Subject to the constraints of the exchange mechanisms in use, a conforming metadata instance MAY be
- 200 rooted by either an <md:EntityDescriptor> or <md:EntitiesDescriptor> element. This profile
- further applies to any <md:RoleDescriptor> element (or any derived elements and types) that may be
- 202 included.
- 203 Within the context of a particular role (and the protocols it supports, as expressed in its
- 204 protocolSupportEnumeration attribute), any and all cryptographic keys that are known to be valid at
- 205 the time of metadata production MUST appear, each in its own <md: KeyDescriptor> element, with the
- appropriate use attribute if the key is usable only for a single purpose. This includes not only signing and
- 207 encryption keys, but also any keys used to establish mutual authentication with technologies such as TLS/
- 208 SSL.

216

232

- Signing or transport authentication keys intended for future use MAY be included as a means of preparing
- 210 for migration from an older to a newer key.
- 211 Compromised keys MUST be removed from an entity's metadata; the metadata producer MUST NOT rely
- on the metadata consumer utilizing online or offline mechanisms for verifying the validity of a key (e.g.
- 213 X.509 revocation lists, OCSP, etc.). The exact time by which a compromise must be reflected in metadata
- 214 is left to the requirements of the parties involved, the metadata's validity period (as defined by a
- 215 validUntil or cacheDuration attribute), and the exchange mechanism in use.

2.5.1 Key Representation

- 217 Each key included in a metadata role MUST be placed within its own <md: KeyDescriptor> element
- 218 and expressed using the <ds: KeyInfo> element within. One or more of the following representations
- 219 within a <ds: KeyInfo> element MUST be present:
- 220 <ds:KeyValue>
- <ds:X509Certificate> (child element of <ds:X509Data>)
- 222 In the case of the latter, only a single certificate is permitted. If both forms are used, then they MUST
- 223 represent the same key.
- 224 Any other representation in the form of a <ds:KeyInfo> child element (such as <ds:KeyName>,
- 225 <ds:X509SubjectName>, <ds:X509IssuerSerial>, etc.) MAY appear, but MUST NOT be required
- in order to identify the key (they are hints only).
- In the case of an X.509 certificate, there are no requirements as to the content of the certificate apart from
- the requirement that it contain the appropriate public key. Specifically, the certificate MAY be expired, not
- yet valid, carry critical or non-critical extensions or usage flags, and contain any subject or issuer.
- However, in the interest of interoperability, it is RECOMMENDED that any certificates appearing be valid
- 231 during the containing metadata's validity period.

2.6 Metadata Consumer Requirements

- 233 A metadata consumer MUST have the ability to fully provision and configure itself based on the content of
- a metadata instance that it has accepted (see section 2.3), within the constraints of the information
- represented by the SAML V2.0 metadata specification [SAML2Meta] and any profiles that make use of it.
- A consumer need not provision policy that is outside the scope of metadata, but MUST have the ability to
- interoperate with the entities described by a metadata instance that it accepts, constrained by whatever
- 238 default policies it applies.

13 draft-sstc-metadata-iop-01
14 Copyright © OASIS Open 2008, All

- Subject to the constraints of the exchange mechanism(s) in use, a metadata consumer MUST be able to
- 240 process instances rooted with either an <md:EntityDescriptor> or <md:EntitiesDescriptor>
- element. When processing an <md:EntitiesDescriptor> element, each <md:EntityDescriptor>
- element contained within it MUST be processed in accordance with this profile (subject to their validity).

243 2.6.1 Key Processing

- 244 Each key expressed by a <md: KeyDescriptor> element within a particular role MUST be accepted
- 245 when processing messages or assertions in the context of that role. Specifically, any signatures or
- transport communications (e.g. TLS/SSL sessions) verifiable with a signing key MUST be accepted, and
- 247 any encryption keys found may be used to encrypt messages or assertions to the containing entity.
- 248 Subsequent to accepting a metadata instance, a consumer MUST NOT apply additional criteria of any
- kind on the acceptance, or validity, of the keys found within it or their use at runtime. Specifically,
- consumers SHALL NOT apply any online or offline techniques including, but not limited to, X.509 path
- validation or revocation lists, OCSP responders, etc.
- The following key representations within a <ds:KeyInfo> element MUST be supported:
- <ds:X509Certificate> (child element of <ds:X509Data>)
- 255 In the case of the latter, a metadata consumer MUST extract the public key found in the certificate and
- MUST NOT honor, interpret, or make use of any of the information found in the certificate other than as an
- 257 aid in identifying the appropriate key to try (based, for example, on information found at runtime in an XML
- 258 digital signature's <ds: KeyInfo> element or the certificate presented by a transport peer).
- A metadata consumer, when implementing authentication of a transport peer via TLS/SSL, MAY retain the
- checking of server certificate names (e.g. subject cn or subjectAltName) in accordance with common
- practice, but even then it MUST accept a properly named certificate that contains a public key that
- 262 corresponds to a valid key found in that peer's metadata, even if the exact certificate presented is not
- 263 found in that metadata.

266

16

- The effect of these rules are to require all runtime decisions to be made solely on the basis of key
- comparisons, and not on any traditionally certificate-influenced basis.

2.7 Security Considerations

- 267 Experience has shown that the most frustrating part of using SAML (and many similar technologies) is that
- 268 products approach the use of cryptography and trust in wildly inconsistent ways, and often the libraries
- that such products depend on do the same in their own domains. Key management is hard, and often
- relies on complicated tools with cryptic output. Standards only help insofar as they can be understood and
- 271 widely implemented; this has generally not occurred above a basic level of cryptographic correctness.
- A formal PKI is a tremendously complex, and some would say intractable, goal; it could be argued that
- 273 SAML itself is a reaction to this. Often, the security of deployments is based on a presumption that
- 274 required practices like revocation checking are being performed, when in fact they are not.
- 275 The purpose of this profile is to guarantee that in a correct implementation, all security considerations not
- deriving from the particular cryptography used (i.e. algorithm strength, key sizes) can be strictly confined
- 277 to the space of metadata exchange and acceptance, and not in the space of runtime processing of
- 278 messages. If an implementation can be shown to rely solely on metadata to derive trust, it can be
- 279 reasoned about in a much simpler way, and the security exposures can be well understood by a wider
- range of deployers.
- 281 Furthermore, this approach accomplishes a number of practical goals:

15 draft-sstc-metadata-iop-01

simplifying ordinary implementations and deployments

283

285

- reducing the technical foundation required to understand and use implementations
- scaling the provisioning of federated relationships (via processing of metadata batches)
 - radically simplifying interactions between existing federated deployments (i.e. interfederation)

Most importantly, these goals can be accomplished without sacrificing security. Too often, the reaction to security complexity is to produce competing approaches that start by rejecting the notion that a substantial degree of security is achievable in the general case.

- Another benefit of this profile is to produce a greater awareness of the importance of securing the
 exchange of metadata. Deployers have sometimes tended to ignore this issue by falling back on the
 assumption that the underlying PKI would provide the real security of the system, resulting in other
 exposures due to insecure provisioning of other important information. With this profile, essentially all
 security in the system derives from the metadata.
- However, with these points made, it is the case that a number of important exposures arise from the reliance on metadata alone to control runtime trust decisions. In particular, metadata becomes a critical tool for the revocation of compromised sites and keys, and all of the standard practices in the use of tools like CRLs become relevant to the consumption of metadata. The specification has the mechanisms to address these issues, but they have to be used.
- For example, distributing signed metadata without an expiration over an untrusted channel (e.g. posting it on a public web site) creates an immediate exposure. An attacker can corrupt the channel and substitute an old metadata file containing a compromised key and proceed to use that key together with other attacks to impersonate a site. Preventing this is simple; repeatedly expire and reissue the metadata, thus limiting the window of exposure just as a CRL does.
- A broad set of concerns arises in the dynamic exchange of metadata self-published by a site. In such cases, it may seem untenable to simply trust someone to properly identify their own key, and of course it may be. But the solution here is not to constrain the acceptance of that key, but to secure the exchange and acceptance of the metadata. Traditional PKI protections can be applied to that document and/or its exchange, subsequently leveraging that protection to establish trust in the key within the metadata.
